# **Machine Learning Engineer Nanodegree**

#### Model Evaluation & Validation

### **Project 1: Predicting Boston Housing Prices**

Welcome to the first project of the Machine Learning Engineer Nanodegree! In this notebook, some template code has already been written. You will need to implement additional functionality to successfully answer all of the questions for this project. Unless it is requested, do not modify any of the code that has already been included. In this template code, there are four sections which you must complete to successfully produce a prediction with your model. Each section where you will write code is preceded by a **STEP X** header with comments describing what must be done. Please read the instructions carefully!

In addition to implementing code, there will be questions that you must answer that relate to the project and your implementation. Each section where you will answer a question is preceded by a **QUESTION X** header. Be sure that you have carefully read each question and provide thorough answers in the text boxes that begin with "**Answer**:". Your project submission will be evaluated based on your answers to each of the questions.

A description of the dataset can be found <a href="https://archive.ics.uci.edu/ml/datasets/Housing">https://archive.ics.uci.edu/ml/datasets/Housing</a>), which is provided by the UCI Machine Learning Repository.

# **Getting Started**

To familiarize yourself with an iPython Notebook, **try double clicking on this cell**. You will notice that the text changes so that all the formatting is removed. This allows you to make edits to the block of text you see here. This block of text (and mostly anything that's not code) is written using Markdown (http://daringfireball.net/projects/markdown/syntax), which is a way to format text using headers, links, italics, and many other options! Whether you're editing a Markdown text block or a code block (like the one below), you can use the keyboard shortcut **Shift + Enter** or **Shift + Return** to execute the code or text block. In this case, it will show the formatted text.

Let's start by setting up some code we will need to get the rest of the project up and running. Use the keyboard shortcut mentioned above on the following code block to execute it. Alternatively, depending on your iPython Notebook program, you can press the **Play** button in the hotbar. You'll know the code block executes successfully if the message "Boston Housing dataset loaded successfully!" is printed.

```
In [217]: # Importing a few necessary libraries
          import numpy as np
          import matplotlib.pyplot as pl
          from sklearn import datasets
          from sklearn.tree import DecisionTreeRegressor
          # Make matplotlib show our plots inline (nicely formatted in the notebook)
          %matplotlib inline
          # Create our client's feature set for which we will be predicting a selling price
          CLIENT FEATURES = [[11.95, 0.00, 18.100, 0, 0.6590, 5.6090, 90.00, 1.385, 24, 680.
          0, 20.20, 332.09, 12.13]]
          # Load the Boston Housing dataset into the city data variable
          city data = datasets.load boston()
          # Initialize the housing prices and housing features
          housing prices = city data.target
          housing features = city data.data
          print "Boston Housing dataset loaded successfully!"
```

Boston Housing dataset loaded successfully!

# Statistical Analysis and Data Exploration

In this first section of the project, you will quickly investigate a few basic statistics about the dataset you are working with. In addition, you'll look at the client's feature set in <code>CLIENT\_FEATURES</code> and see how this particular sample relates to the features of the dataset. Familiarizing yourself with the data through an explorative process is a fundamental practice to help you better understand your results.

## Step 1

In the code block below, use the imported <code>numpy</code> library to calculate the requested statistics. You will need to replace each <code>None</code> you find with the appropriate <code>numpy</code> coding for the proper statistic to be printed. Be sure to execute the code block each time to test if your implementation is working successfully. The print statements will show the statistics you calculate!

```
In [218]: m, n = np.shape(city data.data)
          # Number of houses in the dataset
          total houses = m
          # Number of features in the dataset
          total features = n
          # Minimum housing value in the dataset
          minimum price = np.min(housing prices)
          # Maximum housing value in the dataset
          maximum price = np.max(housing prices)
          # Mean house value of the dataset
          mean price = np.mean(housing prices)
          # Median house value of the dataset
          median_price = np.median(housing_prices)
          # Standard deviation of housing values of the dataset
          std dev = np.std(housing prices)
          # Show the calculated statistics
          print "Boston Housing dataset statistics (in $1000's):\n"
          print "Total number of houses:", total houses
          print "Total number of features:", total features
          print "Minimum house price:", minimum price
          print "Maximum house price:", maximum price
          print "Mean house price: {0:.3f}".format(mean price)
          print "Median house price:", median price
          print "Standard deviation of house price: {0:.3f}".format(std dev)
         Boston Housing dataset statistics (in $1000's):
         Total number of houses: 506
         Total number of features: 13
         Minimum house price: 5.0
         Maximum house price: 50.0
         Mean house price: 22.533
         Median house price: 21.2
```

As a reminder, you can view a description of the Boston Housing dataset <a href="https://archive.ics.uci.edu/ml/datasets/">here (https://archive.ics.uci.edu/ml/datasets//here/housing</a>), where you can find the different features under **Attribute Information**. The MEDV attribute relates to the values stored in our housing prices variable, so we do not consider that a feature of the data.

Of the features available for each data point, choose three that you feel are significant and give a brief description for each of what they measure.

Remember, you can double click the text box below to add your answer!

Standard deviation of house price: 9.188

Answer: RAD, TAX and RM. RAD: The accessibility to radial roads leading out of the city. TAX: The property tax in full value calculated per \$10,000. RM: Average number of rooms per dwelling.

Using your client's feature set CLIENT\_FEATURES, which values correspond with the features you've chosen above? **Hint:** Run the code block below to see the client's data.

```
In [219]: print CLIENT_FEATURES

[[11.95, 0.0, 18.1, 0, 0.659, 5.609, 90.0, 1.385, 24, 680.0, 20.2, 332.09, 12.13
]
```

Answer: RM: 5.609, RAD: 24, TAX: 680.0

# **Evaluating Model Performance**

In this second section of the project, you will begin to develop the tools necessary for a model to make a prediction. Being able to accurately evaluate each model's performance through the use of these tools helps to greatly reinforce the confidence in your predictions.

### Step 2

In the code block below, you will need to implement code so that the shuffle split data function does the following:

- Randomly shuffle the input data X and target labels (housing values) y.
- Split the data into training and testing subsets, holding 30% of the data for testing.

If you use any functions not already acessible from the imported libraries above, remember to include your import statement below as well!

Ensure that you have executed the code block once you are done. You'll know if the <code>shuffle\_split\_data</code> function is working if the statement "Successfully shuffled and split the data!" is printed.

```
In [220]: # Put any import statements you need for this code block here
          from sklearn import cross validation
          def shuffle_split_data(X, y):
              """ Shuffles and splits data into 70% training and 30% testing subsets,
                  then returns the training and testing subsets. """
              # Shuffle and split the data
              X train, X test, y train, y test = cross validation.train test split(X, y, tes
          t size=0.3, train size=0.7)
              ,,,
              X train = None
              y train = None
              X test = None
              y_test = None
              # Return the training and testing data subsets
              return X_train, y_train, X_test, y_test
          # Test shuffle split data
          try:
              X_train, y_train, X_test, y_test = shuffle_split_data(housing_features, housin
          g prices)
              print "Successfully shuffled and split the data!"
              print "Something went wrong with shuffling and splitting the data."
```

Successfully shuffled and split the data!

#### **Question 4**

Why do we split the data into training and testing subsets for our model?

#### Answer:

- (1) To give an estimate of performance on an independent dataset.
- (2) Serves as a check on overfitting.

## Step 3

In the code block below, you will need to implement code so that the  $performance\_metric$  function does the following:

Perform a total error calculation between the true values of the y labels y\_true and the predicted values of the y labels y predict.

You will need to first choose an appropriate performance metric for this problem. See <a href="mailto:thesa: learn.org/stable/modules/classes.html#sklearn-metrics-metrics">thesa: learn.org/stable/modules/classes.html#sklearn-metrics-metrics</a>) to view a list of available metric functions. **Hint:** Look at the question below to see a list of the metrics that were covered in the supporting course for this project.

Once you have determined which metric you will use, remember to include the necessary import statement as well! Ensure that you have executed the code block once you are done. You'll know if the performance\_metric function is working if the statement "Successfully performed a metric calculation!" is printed.

Successfully performed a metric calculation!

#### **Question 4**

Which performance metric below did you find was most appropriate for predicting housing prices and analyzing the total error. Why?

- Accuracy
- Precision
- Recall
- F1 Score
- Mean Squared Error (MSE)
- Mean Absolute Error (MAE)

Answer: Mean Squared Error (MSE). Because this is a regression problem, Mean Squared Error (MSE) and Mean Absolute Error (MAE) can be appropriate for this problem. But the advantage of MSE over MAE is that it automatically converts all the errors as positives, emphasizes larger errors rather than smaller errors (since the square error takes the effect), and form calculus is differentiable which allows us to find the minimum or maximum values.

### Step 4 (Final Step)

In the code block below, you will need to implement code so that the fit model function does the following:

- Create a scoring function using the same performance metric as in **Step 2**. See the <a href="make\_scorer.documentation">sklearn\_make\_scorer.documentation</a> (<a href="http://scikit-learn.org/stable/modules/generated/sklearn.metrics.make\_scorer.html">http://scikit-learn.org/stable/modules/generated/sklearn.metrics.make\_scorer.html</a>).
- Build a GridSearchCV object using regressor, parameters, and scoring\_function. See the <u>sklearn</u> documentation on GridSearchCV (http://scikit-learn.org/stable/modules/generated /sklearn.grid\_search.GridSearchCV.html).

When building the scoring function and GridSearchCV object, be sure that you read the parameters documentation thoroughly. It is not always the case that a default parameter for a function is the appropriate setting for the problem you are working on.

Since you are using sklearn functions, remember to include the necessary import statements below as well! Ensure that you have executed the code block once you are done. You'll know if the fit\_model function is working if the statement "Successfully fit a model to the data!" is printed.

```
In [222]: # Put any import statements you need for this code block
          from sklearn.metrics import make scorer, mean squared error
          from sklearn import grid search
          def fit model(X, y):
              """ Tunes a decision tree regressor model using GridSearchCV on the input data
                  and target labels y and returns this optimal model. """
              # Create a decision tree regressor object
              regressor = DecisionTreeRegressor()
              # Set up the parameters we wish to tune
              parameters = \{ \text{'max depth'}: (1,2,3,4,5,6,7,8,9,10) \}
              # Make an appropriate scoring function
              scoring function = make scorer(mean squared error, greater is better=False)
              # Make the GridSearchCV object
              reg = grid search.GridSearchCV(regressor, parameters, scoring=scoring function
              # Fit the learner to the data to obtain the optimal model with tuned parameter
              reg.fit(X, y)
              # Return the optimal model
              return reg
          # Test fit_model on entire dataset
              reg = fit model(housing features, housing prices)
              print "Successfully fit a model!"
          except:
              print "Something went wrong with fitting a model."
```

Successfully fit a model!

What is the grid search algorithm and when is it applicable?

Answer: Grid search is used to obtain the best possible model by creating a set of models with different parameters and evaluating each of them using cross-validation. It then selects the model which has the highest score or which performed the best.[3]

#### **Question 6**

What is cross-validation, and how is it performed on a model? Why would cross-validation be helpful when using grid search?

Answer: We first create two subsets of the given dataset, namely training and testing data sets. Then we create our model using the training dataset. We then test the performance of this model on the testing data set. This process is called holdout method for cross-validation. In grid search K-Fold Cross-Validation is used. In K-Fold cross-validation the data is divided into k subsets and then the holdout method is repeated k times. Each time, one of the k subsets is used as the test set and the other k-1 subsets are put together to form a training set. Cross-validation is done to overcome overfitting. Cross-validation will be helpful during grid search to determine the performance of each set of models and based on this we can select the best performing model. Cross validation iterators can also be used to directly perform model selection using Grid Search for the optimal hyperparameters of the model. [3][5]

# **Checkpoint!**

You have now successfully completed your last code implementation section. Pat yourself on the back! All of your functions written above will be executed in the remaining sections below, and questions will be asked about various results for you to analyze. To prepare the **Analysis** and **Prediction** sections, you will need to intialize the two functions below. Remember, there's no need to implement any more code, so sit back and execute the code blocks! Some code comments are provided if you find yourself interested in the functionality.

```
In [223]: def learning_curves(X_train, y_train, X_test, y_test):
              """ Calculates the performance of several models with varying sizes of trainin
          g data.
                  The learning and testing error rates for each model are then plotted. """
              print "Creating learning curve graphs for max depths of 1, 3, 6, and 10. . ."
              # Create the figure window
              fig = pl.figure(figsize=(10,8))
              # We will vary the training set size so that we have 50 different sizes
              sizes = np.round(np.linspace(1, len(X train), 50))
              train err = np.zeros(len(sizes))
              test err = np.zeros(len(sizes))
              # Create four different models based on max depth
              for k, depth in enumerate([1,3,6,10]):
                  for i, s in enumerate(sizes):
                      # Setup a decision tree regressor so that it learns a tree with max de
          pth = depth
                      regressor = DecisionTreeRegressor(max depth = depth)
                      # Fit the learner to the training data
                      regressor.fit(X_train[:s], y_train[:s])
                      # Find the performance on the training set
                      train_err[i] = performance_metric(y_train[:s], regressor.predict(X_tra
          in[:s]))
                      # Find the performance on the testing set
                      test_err[i] = performance_metric(y_test, regressor.predict(X_test))
                  # Subplot the learning curve graph
                  ax = fig.add subplot(2, 2, k+1)
                  ax.plot(sizes, test err, lw = 2, label = 'Testing Error')
                  ax.plot(sizes, train err, lw = 2, label = 'Training Error')
                  ax.legend()
                  ax.set title('max depth = %s'%(depth))
                  ax.set xlabel('Number of Data Points in Training Set')
                  ax.set_ylabel('Total Error')
                  ax.set xlim([0, len(X train)])
              # Visual aesthetics
              fig.suptitle('Decision Tree Regressor Learning Performances', fontsize=18, y=1
          .03)
              fig.tight layout()
              fig.show()
```

```

              pl.plot(max_depth, test err, lw=2, label = 'Testing Error')
              pl.plot(max_depth, train_err, lw=2, label = 'Training Error')
              pl.legend()
              pl.xlabel('Maximum Depth')
              pl.ylabel('Total Error')
              pl.show()
```

# **Analyzing Model Performance**

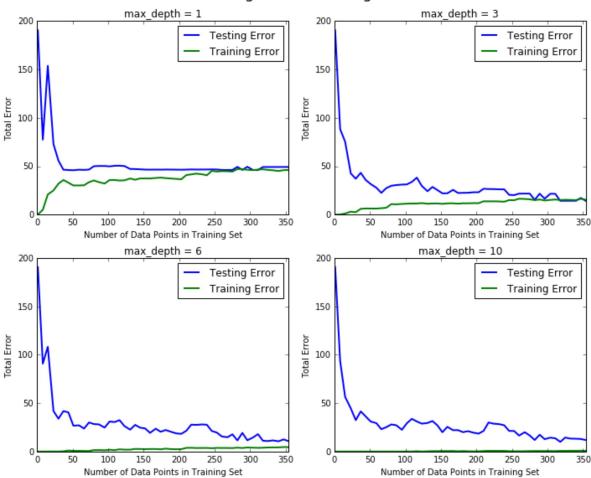

In this third section of the project, you'll take a look at several models' learning and testing error rates on various subsets of training data. Additionally, you'll investigate one particular algorithm with an increasing max\_depth parameter on the full training set to observe how model complexity affects learning and testing errors. Graphing your model's performance based on varying criteria can be beneficial in the analysis process, such as visualizing behavior that may not have been apparent from the results alone.

Creating learning curve graphs for max depths of 1, 3, 6, and 10. . .

C:\Anaconda2\lib\site-packages\ipykernel\\_\_main\_\_.py:24: DeprecationWarning: usi ng a non-integer number instead of an integer will result in an error in the fut ure

#### **Decision Tree Regressor Learning Performances**

### **Question 7**

Choose one of the learning curve graphs that are created above. What is the max depth for the chosen model? As the size of the training set increases, what happens to the training error? What happens to the testing error?

Answer: The max depth for the chosen model is 6. As the size of the training set increases, the training error increases gradually, at a slow and almost steady rate. And testing error keeps on decreasing slowly and gradually.

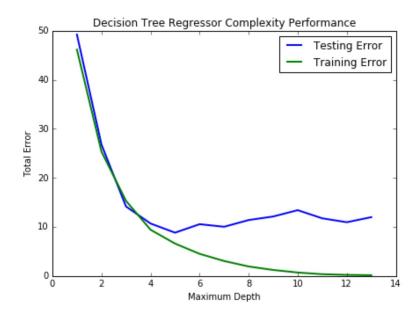

Look at the learning curve graphs for the model with a max depth of 1 and a max depth of 10. When the model is using the full training set, does it suffer from high bias or high variance when the max depth is 1? What about when the max depth is 10?

Answer: Model is suffering from high bias when the max depth is 1 i.e. Underfitting. Model is suffering from high variance when the max depth is 10 i.e. Overfitting.[4]

When max depth is 1, both the training error and testing error are high and the difference between training error and testing error is minimum, the model performs poorly and is unable to train correctly and underfitting is taking place. So, we can say that when max depth is 1 the model suffers from high bias.

When max depth is 10 training error is almost none, but the testing error is high and the difference between training error and testing error is high, the model just appears to be training perfectly but still gives testing error, hence overfitting is taking place. So, we can say that when max depth is 10 the model suffers from high variance.

In [226]: model\_complexity(X\_train, y\_train, X\_test, y\_test)
Creating a model complexity graph. . .

### **Question 9**

From the model complexity graph above, describe the training and testing errors as the max depth increases. Based on your interpretation of the graph, which max depth results in a model that best generalizes the dataset? Why?

Answer: As the max depth increases, the training error decreases constantly and the testing error decreases upto a certain point but then starts increasing again. According to the graph, max depth value between 4 and 6 is best to generalize the dataset because in this region the problem of underfitting and overfitting does not occur, while keeping the testing error minimum.

### **Model Prediction**

In this final section of the project, you will make a prediction on the client's feature set using an optimized model from fit\_model. To answer the following questions, it is recommended that you run the code blocks several times and use the median or mean value of the results.

#### **Question 10**

Using grid search on the entire dataset, what is the optimal max\_depth parameter for your model? How does this result compare to your intial intuition?

Hint: Run the code block below to see the max depth produced by your optimized model.

```
In [227]: print "Final model optimal parameters:", reg.best_params_
Final model optimal parameters: {'max_depth': 4}
```

Answer: Running the code blocks multiple times, I notice that the max\_depth value changes between 4 and 7. The max\_depth value between 4 to 7 is the optimal parameter for the model. This compares precisely to my initial intuition.

#### **Question 11**

With your parameter-tuned model, what is the best selling price for your client's home? How does this selling price compare to the basic statistics you calculated on the dataset?

Hint: Run the code block below to have your parameter-tuned model make a prediction on the client's home.

Answer: With the parameter-tuned model, the best selling price for the client's home is \$21,600. This selling price is only \$900 less than the mean house price and \$400 more than the median house price.

## **Question 12 (Final Question):**

In a few sentences, discuss whether you would use this model or not to predict the selling price of future clients' homes in the Greater Boston area.

Answer: Yes, I would use this model to predict the selling price of future clients' homes as the predicted price using this model seems accurate looking at the trend of selling price of other homes. Also the predicted price falls in the range of basic statistics performed on the dataset, i.e. it is near to mean house price and median house price.
